

1

Disease Outbreak

INVESTIGATION

2–3 CLASS SESSIONS

ACTIVITY OVERVIEW

NGSS CONNECTIONS

Students participate in a model of the spread of an infectious disease. They analyze data from the model to identify patterns, and then use the patterns supported by the data to determine the cause of the spread of the infectious disease. The problem of diagnosing and treating infectious diseases provides a context for the exploration of cell structure and function that follows.

Review the unit overview and assessment chart for a summary of the NGSS taught and assessed in this activity and how the standards are woven together throughout the unit. Decide in advance which assessments you plan to emphasize.

This unit assesses students on four performance expectations: MS-LS1-1, MS-LS1-2, MS-LS1-6, and MS-LS1-7. It also builds toward more complete understanding of concepts related to MS-LS1-3: Use argument supported by evidence for how the body is a system of interacting subsystems composed of groups of cells. MS-LS1-3 is assessed in the Body Systems unit of Issues and Life Science.

NGSS CORRELATIONS

Performance Expectations

Working towards MS-LS1-1: Conduct an investigation to provide evidence that living things are made of cells; either one cell or many different numbers and types of cells.

Disciplinary Core Ideas

MS-LS1.A Structure and Function: All living things are made up of cells, which is the smallest unit that can be said to be alive. An organism may consist of one single cell (unicellular) or many different numbers and types of cells (multicellular).

Science and Engineering Practices

Analyzing and Interpreting Data: Construct and interpret graphical displays of data to identify linear and nonlinear relationships. Analyze and interpret data to provide evidence for phenomena.

Using Mathematics and Computational Thinking: Use mathematical representations to describe and/or support scientific conclusions and design solutions.

Constructing Explanations and Designing Solutions: Apply scientific ideas to construct an explanation for real-world phenomena, examples, or events.

Connections to Nature of Science: Scientific knowledge can describe the consequences of actions but does not necessarily prescribe the decisions that society takes.

Crosscutting Concepts

Patterns: Patterns can be used to identify cause and effect relationships.

Cause and Effect: Cause and effect relationships may be used to predict phenomena in natural or designed systems.

Common Core State Standards— ELA/Literacy

RST.6-8.3: Follow precisely a multistep procedure when carrying out experiments, taking measurements, or performing technical tasks.

WHAT STUDENTS DO

Students model the spread of an infectious disease by simulating participation in various activities that could expose them to infectious agents. They use a model disease indicator to find out if they were infected. Based on the results, the class discusses how infectious diseases are spread, laying a foundation for further analysis of the cause and transmission of the disease.

MATERIALS AND ADVANCE PREPARATION

■ *For the teacher*

- 1 Visual Aid 1.1, “Tracking the Disease: Analyzing Data”
- 1 Scoring Guide: ANALYZING AND INTERPRETING DATA (AID)
- 1 Scoring Guide: EVIDENCE AND TRADEOFFS (E&T)

■ *For the class*

- 5 Place signs
- 1 set of 15 Event and Action dropper bottles
- 15 number cubes

- 2 dropper bottles of Disease Indicator (phenolphthalein solution)
- * 1 bucket (or other similar container) to collect liquid waste
- * distilled water

- *For each group of four students*
 - 1 graduated cylinder (50-mL)
 - 1 set of colored pencils

- *For each student*
 - 1 plastic cup (9-oz)
 - * graph paper
 - * paper towels
 - * 1 pair of chemical splash goggles
 - 1 safety contract (optional)
 - 1 Student Sheet 1.1, “Tracking the Disease: Collecting Data”
 - 1 Student Sheet 1.2, “Tracking the Disease: Analyzing Data”
 - 1 Scoring Guide: ANALYZING AND INTERPRETING DATA (AID) (optional)
 - 1 Scoring Guide: EVIDENCE AND TRADEOFFS (E&T) (optional)

**not supplied in kit*

Tape the five Place signs in different locations around the room. Place the dropper bottles for the appropriate “Actions” under each Place sign. Place three number cubes at each station.

Parts A and B should be completed during one class session, and Part C should be completed during the following class session. This will prevent students from one of your classes telling other students the results before they collect their own data.

If this is the first SEPUP unit you will teach, see Teacher Resources II, “Diverse Learners,” and Teacher Resources III, “Assessment,” for detailed suggestions for using the Analysis items, Extensions, literacy strategies, and Assessment System provided throughout the course.

SAFETY NOTE

Make sure students wear chemical splash goggles and use caution when handling solutions. The chemicals used in this activity are sodium carbonate (in the bottle for Activity 1 Location C) and phenolphthalein pH indicator (the “Disease Indicator”). These chemicals can cause skin irritation. Thoroughly rinse any area that comes into direct contact with laboratory chemicals and make sure students wash their hands thoroughly. We recommend the use of lab aprons in this activity.

DISPOSAL

At the end of the activity, direct students to dispose of all solutions in the waste container. It is safe for the solutions in this laboratory—2% sodium carbonate and phenolphthalein solution—to be disposed of by diluting and pouring them down the drain, but it is important to model proper collection and disposal of liquids, especially those that have not yet been identified by students.

To ensure that “infection” occurs, at least four students must visit the “Picnic at the Lake” place each simulated day. Monitor their movements to make sure there are several students at each station each day. If you have more than one class, consider combining their data or obtaining data from another teacher teaching the same class in order to increase the sample size for the simulation.

TEACHING SUMMARY

GET STARTED

1. Review what students already know about disease.
 - a. Ask students, “What causes disease?”
 - b. Introduce infectious disease and ask students to suggest several more infectious diseases and identify their causes.
 - c. Expand the discussion of infectious diseases by asking, “In what ways are people exposed to infectious diseases?”

DO THE ACTIVITY

2. If you have not previously done so, introduce safety in the science classroom.
 - a. Distribute the safety contract and guidelines you are using and review your expectations for classroom safety.
 - b. Point out the locations of safety equipment in the classroom, and review when and how to use all safety equipment.
 - c. Have students sign and take the safety agreement home for a parent or guardian to read and sign.
3. Students conduct the activity to model an infectious disease outbreak.
 - a. Hand out Student Sheet 1.1, “Tracking the Disease: Collecting Data,” and explain how students will model the “outbreak” of an infectious disease.
 - b. Point out the Place signs around the room, and have student groups decide where they will go the first day, choosing from one of the five Place cards.

- c. Have students continue to move among locations and roll the number cube to determine their three actions.
 - d. Let students know where you will be stationed so they can come to you for “testing” after they finish visiting three locations.
4. The class analyzes its data to determine the source of the disease.
- a. Display Visual Aid 1.1, “Tracking the Disease: Analyzing Data,” as you collect and record the class data.
 - b. Support students as they construct and discuss a bar graph of the number of infected people at each place using “Bar Graphing Checklist” in Appendix C of the Student Book, if needed.
 - c. After students have created their graphs, begin a discussion of the results by asking, “What patterns do you see in the graphs? What do the patterns tell you about how the infection started?”
 - d. Collect the class’s data about the Action that was the source of the infection.
 - e. For Procedure Step 8e, have students create a second bar graph, this time of infected people for each Action taken at the site of the infection (the lake).
 - f. Introduce scientific evidence, and have students use evidence to determine the source of the infection.
 - g. Distinguish evidence from opinion.

BUILD UNDERSTANDING

5. Introduce crosscutting concepts, and explain how scientists use them to think about the natural world.
- a. Explain that crosscutting concepts bridge disciplines.
 - b. Give an example that makes sense for students.
 - c. Introduce the crosscutting concept of patterns, and relate patterns to this activity.
 - d. Introduce the crosscutting concept of cause and effect: mechanism and explanation.
6. The class discusses and analyzes the model.
- a. (AID ASSESSMENT) If you have not previously done so, introduce the SEPUP Assessment System.
 - b. Explain the expectations for student growth over time.

- c. Introduce the concept of trade-offs to prepare students for Analysis item 2.
- d. (E&T QUICK CHECK) Use Analysis item 2 to assess students' understanding of the concept of trade-offs.

TEACHING STEPS

GET STARTED

1. Review what students already know about disease.

- a. Ask students, “What causes disease?”

Ask students to think about the causes of five or six diseases, such as cardiovascular disease (which can cause heart attacks), lung cancer, the common cold, diabetes, stomach ulcers, and the flu. If there have been other diseases in the news lately, consider adding them to this list. Use this list of diseases and students' ideas to develop the idea that diseases are caused by several factors, including “germs” (colds, most stomach ulcers), genetic factors (some heart attacks), environment (chemicals in the environment causing lung cancer), lifestyle (some heart attacks, some cases of Type II diabetes, some cases of lung cancer), or a combination of these causes.

- b. Introduce infectious disease and ask students to suggest several more infectious diseases and identify their causes.

Introduce the term *infectious* to describe diseases such as colds and the flu. When words are formally defined in an activity, they appear in bold type in the Key Vocabulary list. Encourage students to use these words when talking or writing about science. During discussions listen for these words to see if students are using them correctly. Decide how you will support students' understanding of the vocabulary—perhaps by setting up a word wall in the classroom. For more suggestions on ways to develop students' understanding of and proficiency with scientific vocabulary, see the section on Vocabulary Development in Teacher Resources II, “Diverse Learners.”

Students are likely to suggest that diseases are caused by bacteria, viruses, and germs. Explain that the germs that cause diseases are often called infectious agents. Ask them if they know any more about what these agents are or how they work. Accept students' answers for now, and explain that they will learn more about infectious agents and about how they make people sick during this unit.

- c. Expand the discussion of infectious disease by asking, “In what ways are people exposed to infectious diseases?”

Students are likely to focus on the idea that infectious diseases are those that are spread directly from person to person. For example, does the type of contact (direct vs. indirect) affect whether a disease is considered infectious? Infectious diseases are transmitted by either direct or indirect contact. Some are transmitted only through direct person-to-person skin contact (e.g., impetigo—a bacterial skin disease) or through contact and the exchange of bodily fluids (e.g., AIDS). However, others are transmitted via contaminated food or water or by touching contaminated surfaces. Raise the issue of diseases transmitted by other organisms, such as insect-borne diseases. Would students categorize those as infectious? Scientists typically do.

DO THE ACTIVITY

2. If you have not previously done so, introduce safety in the science classroom
- Distribute the safety contract and guidelines you are using and review your expectations for classroom safety.

For a sample safety contract and guidelines, see Teacher Resources I, “Course Essentials.”

- Point out the locations of safety equipment in the classroom, and review when and how to use all safety equipment.

Demonstrate how to use emergency safety equipment, including the safety eyewear, eye-and-face wash, fire blanket, and fire extinguisher.

- Have students sign and take the safety agreement home for a parent or guardian to read and sign.

Tell them to return the signed agreements before the date you plan to conduct the next laboratory activity.

3. Discuss problem-solving approaches used in the activity.

- Hand out Student Sheet 1.1, “Tracking the Disease: Collecting Data,” and explain how students will model the “outbreak” of an infectious disease.

Explain that they will go to a variety of locations (around the room) and participate in actions in these locations that may lead to transmission of infectious agents. Through their investigation, they will collect evidence and form a hypothesis for how the disease is spread.

- b. Point out the Place signs around the room, and have students decide where they will go the first day, choosing from one of the five Place cards.

It is important that they not travel together as a group to the same three places. You may wish to assign each student their first place, or encourage students within a group to go to different places on the first day. After they go to that location, they should follow the directions in the Student Book. Depending on their number cube rolls, they may end up participating in one, two, or three different actions, or repeat some actions at each location they visit. Remind them to be sure to select correctly which numbered bottle relates to their roll of the number cube and the directions in the key.

- c. Have students continue to move among locations and roll the number cube to determine their three actions.

It is usually best to have students choose their own places to visit, but monitor the class to be sure that students are fairly evenly distributed among locations. Also confirm that students are conducting the model and recording their actions correctly. You may wish to let them proceed at their own pace or to turn the classroom lights on and off to signal the “Days” of the simulation and allow them to move to their next chosen location. A sample completed Student Sheet 1.1 is provided at the end of the activity.

Teacher's Note: Be sure students understand that based on their three number cube rolls at each place they visit, they might repeat certain actions while missing others. For example, at the Restaurant, they might eat a fish sandwich and get two mosquito bites, while never eating any corn on the cob.

- d. Let students know where you will be stationed so they can come to you for “testing” after they finish visiting three locations.

As students come to you for disease testing, check their Student Sheets to be sure that they visited three locations and recorded their actions. To prevent other classes from finding out where students became infected, it is best to wait until the next day to begin compiling and analyzing the class’s data. If your students tend to misplace their work, collect their Student Sheets, and keep them until the next class session.

4. The class analyzes its data to determine the source of the disease.
- Display Visual Aid 1.1, “Tracking the Disease: Analyzing Data,” as you collect and record the class data.

There are several ways to collect students’ data: by having students stand or raise hands, with clickers, or by using a survey instrument, such as Survey Monkey. The following assumes you are having students stand. For each location (e.g., Place A, The Restaurant), have students who participated stand as you count them. If they became infected, ask them to remain standing while uninfected students sit. In this way, you can fairly quickly collect the data.

Record the number of students who visited each place and the number of students who were infected at each place. As you project these data to the class, students should also record them on Student Sheet 1.2, “Tracking the Disease: Collecting Data,” in the table titled “Analyzing the Locations.” Support students as needed to calculate the percentage of infected individuals by dividing the number of people infected by the number of people who visited the site.

Sample results for Student Sheet 1.2 are provided at the end of the activity. This sample assumes that approximately equal numbers of students visited each location.

- Support students as they construct and discuss a bar graph of the number of infected people at each place using the “Bar Graphing Checklist” in Appendix C of the Student Book if needed.

In Procedure Step 9b, students create a bar graph of infected people at each place. Use the “Bar Graphing Checklist” in Appendix C of the Student Book, as needed, to help students create their graphs.

SAMPLE GRAPH OF ANALYZING THE LOCATIONS

- c. After students have created their graphs, begin a discussion of the results by asking, “What patterns do you see in the graphs? What do the patterns tell you about how the infection started?”

Students should recognize that in the scenario for this activity, the likely source of the infection is the place or places that had the highest number of people infected. If you have time, let students suggest which place(s) to analyze. Unless students have made errors when choosing the activity bottle, the “Picnic at the Lake” is likely to show the highest rate of infection. However, it is statistically possible that another site will have a higher rate than the remaining sites. If time is short, guide them toward analyzing “Picnic at the Lake.” If they are having trouble determining that the lake was the likely location, have all students who did not become infected stand. Ask them which two places they did not visit. It is likely that most of them did not visit the lake. A few exceptions due to errors in selecting activity bottles are possible.

- d. Collect the class’s data about the Action that was the source of the infection.

Collect students' data about each action similarly to how you collected it for each place. For each action at a location (e.g., Place A, The Restaurant, Action 1: Eat a fish sandwich), have students who participated stand as you count them. If they became infected, ask them to remain standing while uninfected students sit. In this way, you can fairly quickly collect the data. On Student Sheet 1.2, record the data on the first table for analyzing the actions. If you choose to analyze two places, record the data from the second place on the second table for analyzing the actions. Support students as needed in calculating the percentages for the last columns of their tables by dividing the number infected by the number participating in each action.

- e. For Procedure Step 9e, have students create a second bar graph, this time of infected people for each Action taken at the site of the infection (the lake).

Students analyze these data to determine the action that was the source of the infection. Since the lake is the source, 100% or nearly 100% of students who went swimming should be positive for infection. Note that a few students who went swimming might be negative because they took drops from the wrong bottle (or vice versa). Explain that not everyone exposed to an infectious agent gets the disease. In some cases, the

immune system is able to fight the disease before any symptoms develop. It is also possible for an individual who didn't attend the picnic to have become infected in another way, such as touching a surface contaminated by an individual suffering from the disease.

SAMPLE GRAPH OF ANALYZING THE ACTIONS AT: LAKE PICNIC

- f. Introduce scientific evidence, and have students use evidence to determine the source of the infection.

In the final step of the Procedure, students discuss what the data they have collected suggests about the source of the disease. Review the definition of evidence provided in the Student Book. Explain that scientists collect information (data) with various tools and strategies, including observation and experimentation. Explain that in this activity, students will use the data they collected from the model about who became infected as evidence to make conclusions, or claims, about the source of the disease. The consideration of evidence is a key step in scientific reasoning and decision making.

- g. Distinguish evidence from opinion.

Explain that evidence is information that supports a claim. In contrast, an opinion is the view someone takes about a certain issue based on their own judgment. An opinion might not be based on evidence. An informed opinion might be based on evidence; however, another person may have a different opinion based on the same evidence. To distinguish evidence from opinion in science, it is helpful to determine if a statement describes information gathered through reliable and appropriate procedures and is likely to be reproducible. The question is: Could someone else gather similar information under similar circumstances? If the answer is yes, the statement is not opinion and is likely evidence.

BUILD UNDERSTANDING

5. Introduce crosscutting concepts, and explain how scientists use them to think about the natural world.

- a. Explain that crosscutting concepts bridge disciplines.

They can be a lens or touchstone through which students make sense of phenomena and deepen their understanding of disciplinary core ideas. Refer students to Appendix G, “Crosscutting Concepts,” in the Student Book and point out the symbols and definitions provided.

- b. Give an example that makes sense for students.

For example, in this activity, students used both the crosscutting concepts of patterns and cause and effect. They used patterns in graphed data to look for cause-and-effect relationships between activities and the disease outbreak. Patterns and cause-and-effect relationships help scientists across disciplines think about their data and how it might explain scientific phenomena.

- c. Introduce the crosscutting concept of patterns, and relate patterns to this activity.

Display the definition and symbol used for patterns in Appendix G, “Crosscutting Concepts.” Explain that pattern can be structural, as shown in the diagram, or a pattern in events, such as the phases of the moon or patterns in a disease outbreak. Point out to students that seeing patterns in nature can lead scientists to organize and classify their observations. It can also lead them to ask questions about relationships and the causes of patterns. Students will look for patterns when they analyze and interpret data, ask questions about the patterns they observe, and suggest cause-and-effect relationships to explain patterns.

- d. Introduce the crosscutting concept of cause and effect.

Scientists investigate and try to explain how things work, and try to figure out what causes various events and patterns. Review the symbol for cause and effect in Appendix G, “Crosscutting Concepts,” which shows a simple diagram of cause and effect, where A (the cause) might or might not cause B (the effect) to happen. For example, in this activity, certain actions might have caused the disease outbreak to happen. That is an example of a simple cause, but sometimes there are more complex causes or chains of events that cause an effect.

6. The class discusses and analyzes the model.
- a. (AID ASSESSMENT) If you have not previously done so, introduce the SEPUP Assessment System.

Explain that Analysis item 1 is the first assessment in this unit, and you will use it to introduce the SEPUP Assessment System to your students. See Teacher Resources III, “Assessment,” to be sure you are familiar with the overall system.

Before assigning the assessment, distribute the analyzing and interpreting data (aid) Scoring Guide and use it to model how the system works. Point out the levels in the first column of the Scoring Guide. Tell students these levels are the same for all Scoring Guides, and range from 0–4. Then review the descriptions of each level. For example, a Level-4 response is complete and correct in all Scoring Guides. Point out that the scores (0–4) are based on the quality of their responses and do not correspond to letter grades. Allow students to refer to the Scoring Guide as they prepare their answers. Be sure that they understand that the Scoring Guides do not include the specific content students must provide in their responses, but explain the overall expectations for responses at various levels of performance on the task. For more information about the Scoring Guides and how you and students can use the system to improve their work, see Teacher Resources III, “Assessment.”

- b. Explain the expectations for student growth over time.

Explain to students that they aren’t expected to always produce complete and correct work on their first attempts. Instead, they should work toward developing consistent Level-3 and Level-4 answers as they become more proficient with the concepts (both disciplinary core ideas and crosscutting concepts) and science and engineering practices being assessed. It is not necessary (or even expected) that an “A” student will always write Level-4 responses, especially at the beginning of the course or when they are introduced to a new scoring guide.

- c. Introduce the concept of trade-offs to prepare students for Analysis item 2.

One of the goals of this curriculum is to teach students that

- decisions often involve trade-offs.
- identifying trade-offs involves analyzing evidence.

In this activity, students review the trade-offs involved in preventing the spread of the disease they modeled. In a decision involving trade-offs, something is given up to gain something else. Since many decisions

involve trade-offs, students should understand that a perfect choice is often not possible. It is possible, however, to recognize and analyze the trade-offs associated with each decision. For example, when asked, "Paper or plastic?" at a store checkout counter, most shoppers make the choice quickly. But there are several trade-offs attached to choosing paper or plastic. A shopper who chooses paper over plastic may do so to avoid generating plastic waste. In requesting the paper bag, though, they are contributing to other environmental problems, such as increased water and energy use, and the higher amounts of solid waste and CO₂ emissions associated with making paper bags. Neither choice is particularly beneficial for the environment, and both choices have a downside. Identifying the trade-offs helps clarify the reasoning that is being applied to make a decision.

To further explore trade-offs, brainstorm with the class a list of decisions they make every day that involve trade-offs. Choose one and talk through the associated trade-offs of deciding one way or another. This practice will familiarize students with ways of identifying and considering trade-offs in this and subsequent activities.

- d. (E&T QUICK CHECK) Use Analysis item 2 to assess students' understanding of the concept of trade-offs.

Analysis item 2 can be used as a formative assessment. Use it to gauge students understanding of trade-offs. See Teacher Resources III: "Assessment" for more information on Quick Checks.

SAMPLE RESPONSES TO ANALYSIS

1. (AID ASSESSMENT) Based on your graph of the class results,
 - a. from where did people get the infectious disease? What evidence supports this claim?

Student responses may vary, depending on how well students separated from each other to visit places. One sample response is shown here:

SAMPLE LEVEL-4 RESPONSE

People got the disease at the Picnic at the Lake. The evidence is that a large percentage of students who visited there became ill. You can see the data in the graph we made.

- b. from what action did people get the infectious disease? What evidence supports this claim?

SAMPLE LEVEL-4 RESPONSE

People got the disease from exposure to water at the lake. The graphs we made provide the evidence. Most, if not all, students who swam at the lake became infected. And people who did not swim at the lake did not become infected.

- c. how certain are you of your answers to a and b? Explain.

Student responses may vary depending on class data. One sample response is shown here:

The high percentage of infections for those who swam compared with participation in other activities makes me pretty sure that it was from swimming at the lake.

2. Imagine that you are the director of the health department in the town where this disease is spreading. It is your job to help prevent people from getting sick with this disease.

- a. Explain what actions you would recommend to try to end the outbreak.

I would recommend that people stay away from the lake. I would put up warning signs around the lake. I would publicize this problem through the Internet, newspapers, and radio stations and suggest that anyone who has recently visited the lake seek medical attention if they become sick.

- b. (E&T QUICK CHECK) A **trade-off** is an exchange of one outcome for another—giving up something that is a benefit or advantage in exchange for something that may be more desirable. What are the trade-offs of your recommendations?

The trade-off is that people cannot use the lake for swimming or picnicking, and so a recreational area has been taken away from everyone. Swimming is good exercise, and people might not have another place to swim. Publicizing this problem may help people get treatment faster, but it might keep people from using the lake even after the outbreak ends.

3. Think about the outbreak of the disease in the community compared with just one person getting sick with the disease. What information can you get from the outbreak that you could not get from one sick person?

An outbreak can provide evidence of the location and type of action that resulted in the spread of the disease. Scientists can identify general symptoms and track the progress of the infection over time. This is because there are more data from lots of people over time than if there is only one infected person.

REVISIT THE GUIDING QUESTION

How do scientists figure out the source of an infectious disease outbreak?

Summarize how the activity modeled the process by which scientists collect and analyze data to determine the spread of an infection.

ACTIVITY RESOURCES

KEY VOCABULARY

evidence

infectious

pattern

trade-offs

BACKGROUND INFORMATION

SPREAD OF INFECTIOUS DISEASES

Statistics compiled from large closed populations (which have no interactions with other populations) during an epidemic of an infectious disease show a bell-shaped curve of the number of infected people over time. Epidemics initially spread slowly; they accelerate as more and more people become infected. This results in an exponential increase in infections until almost all susceptible people in a population have contracted the disease. This activity models only what would happen up to this point in the spread of an infectious disease and does not simulate recovery. In a closed population, the rate of new cases declines once all people have been exposed.

The speed with which an infectious disease spreads will be affected by the infectiousness of the disease, the density and frequency of susceptible people, and the behavior of the susceptible people. The height of the plateau will be affected by how many susceptible people there are. The number of susceptible people is related to the number who have not been vaccinated or have not been exposed to the infectious disease before (e.g., when a new disease enters a population or when many individuals have been born since the last epidemic of the disease).
